Overview

- **Kentucky Renewable Energy Potential:** *Limited*
- **Kentucky Coal Production & Employment:** *Declining*
- **Kentucky's Electricity Portfolio Today:** *Coal*
- **Electricity Expenditures as a Percentage of Household Income:** *It's a lot*
- **United States Electricity Prices, 1998-2012:** *Going up*
- **Another Significance of Electricity to the United States:** *Manufacturing*
- **The Mathematics behind the Models:**
  $Y_{it} = \beta_0 + \sum_{j=1}^{k-1} \beta_j X_{jit} + \beta_{1i} X_{1it} + \alpha_i + \varepsilon_{it}$!
- **Portfolio Model Exercise**

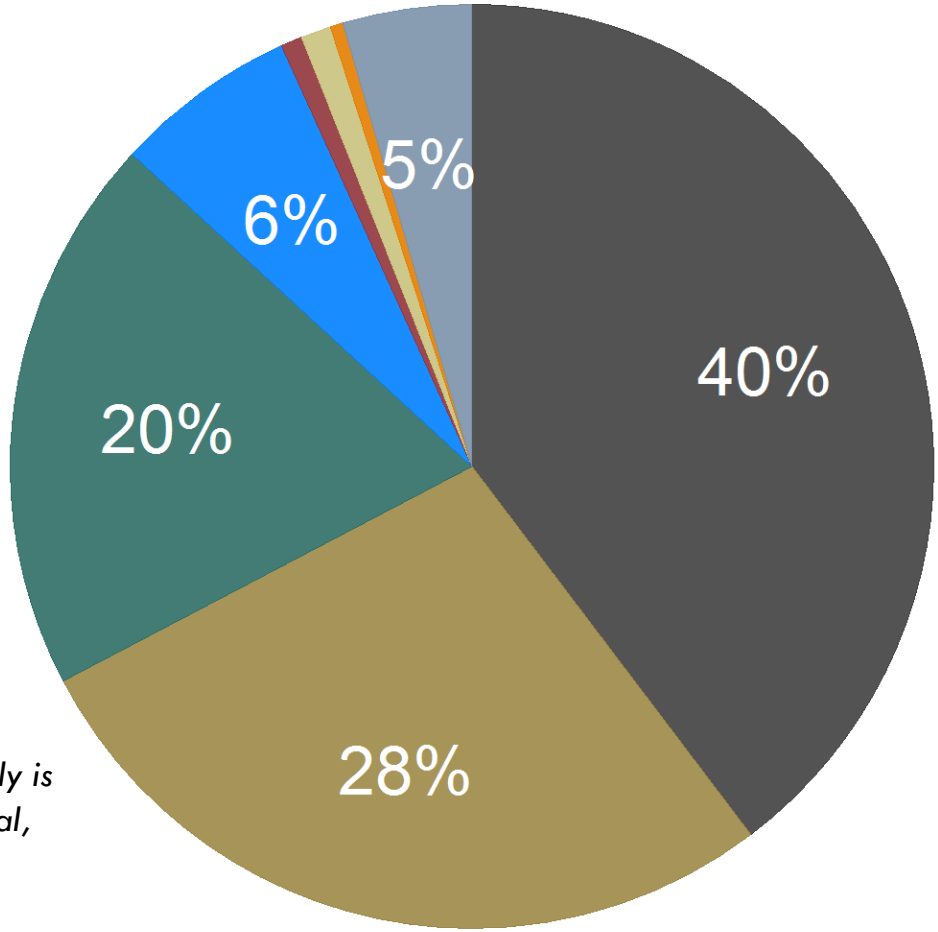
A Quick Introduction to

Kentucky's Electricity Portfolio

United States Electricity Generation by Fuel Type, 2014

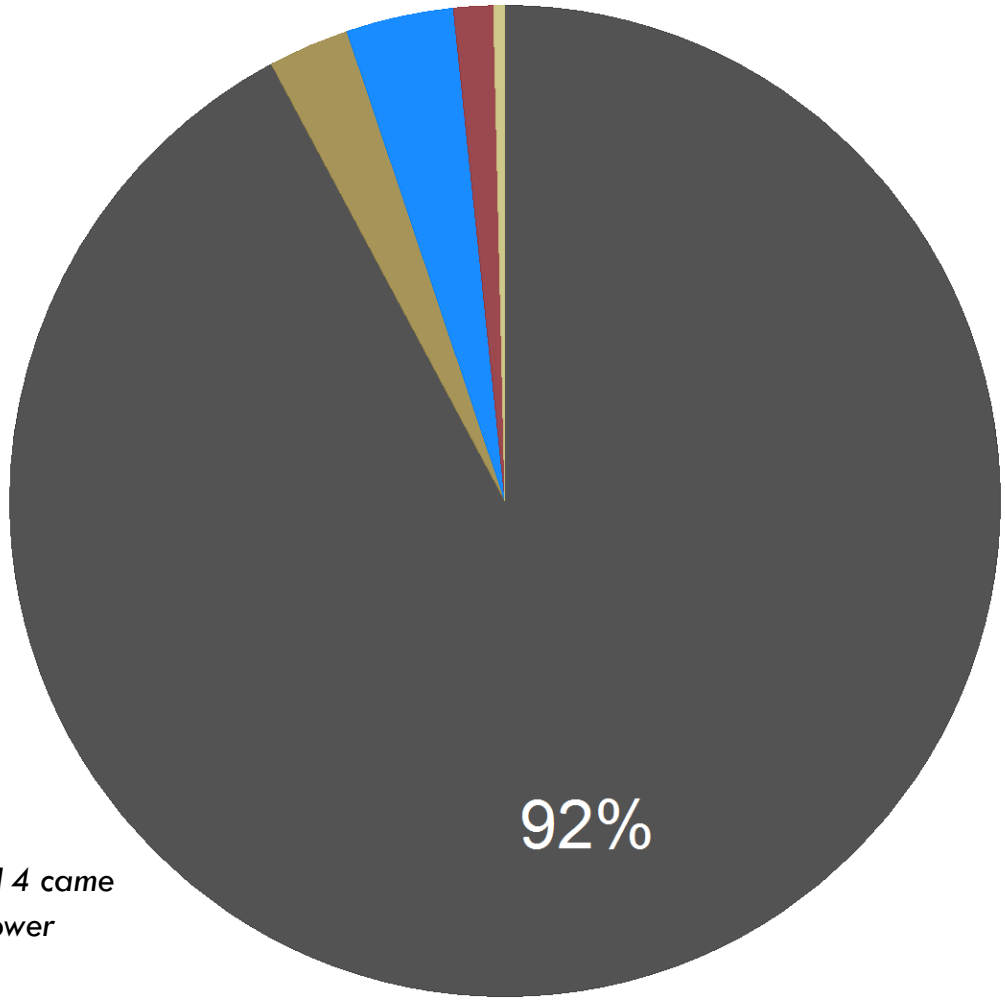


Electricity consumption nationally is relatively balanced between coal, natural gas, nuclear power, hydroelectric, and wind.

Coal
Natural Gas
Nuclear
Hydro
Petroleum
Wood
Solar
Wind

Kentucky Energy Database, EEC-DEDI, 2015

Kentucky Electricity Generation by Fuel Type, 2014



Over 92% of the electricity generated in Kentucky in 2014 came from Kentucky's coal-fired power plants.

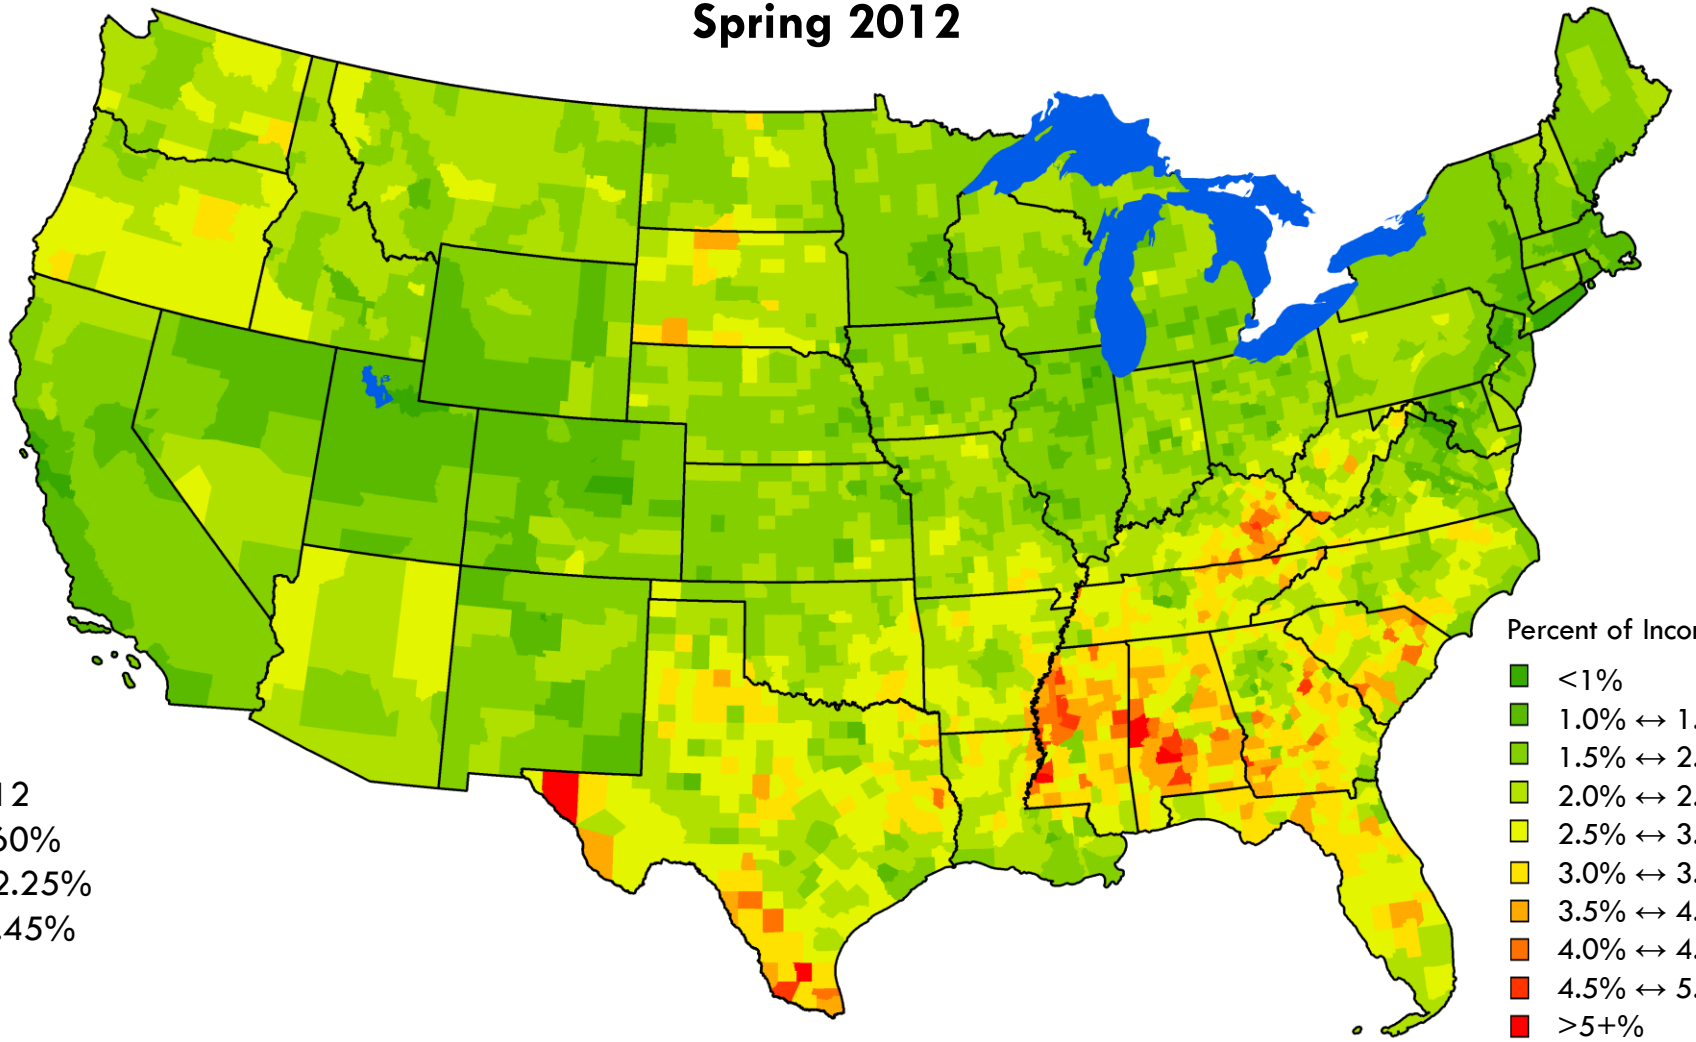
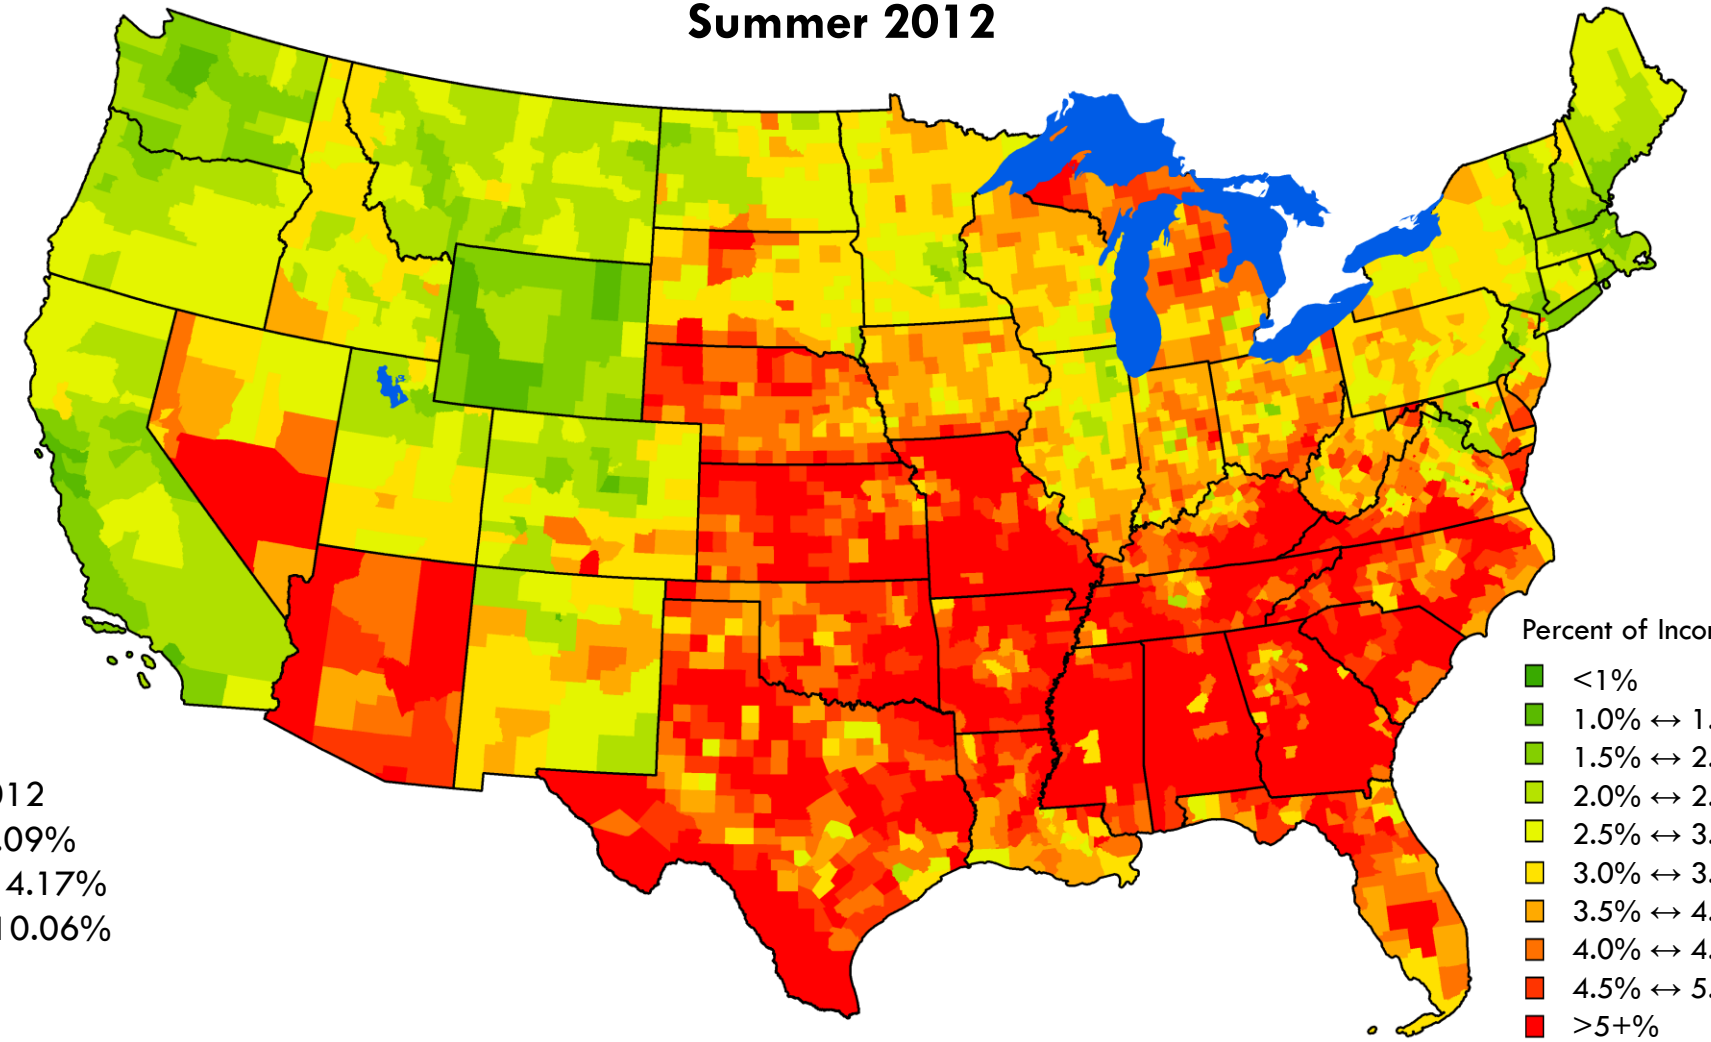
United States Household Electricity Expenditures as a Percentage of Income
Spring 2012



04/2012
Min: 0.60%
Mean: 2.25%
Max: 5.45%

Electricity expenditure data collected by electric service provider by the Energy Information Administration in Form EIA-826 and EIA-861, median household income data collected by the United States Census Bureau American Community Survey. Residential electricity bills vary by household and month not only with electricity prices, but also weather, housing quality, home size, occupancy, personal usage, and method of home heating. Household expenditures for direct heating with fossil fuels such as natural gas, propane, or fuel oil are not reflected in these data.

United States Household Electricity Expenditures as a Percentage of Income
Summer 2012



07/2012
Min: 1.09%
Mean: 4.17%
Max: 10.06%

Electricity expenditure data collected by electric service provider by the Energy Information Administration in Form EIA-826 and EIA-861, median household income data collected by the United States Census Bureau American Community Survey. Residential electricity bills vary by household and month not only with electricity prices, but also weather, housing quality, home size, occupancy, personal usage, and method of home heating. Household expenditures for direct heating with fossil fuels such as natural gas, propane, or fuel oil are not reflected in these data.

Analytical Methodology

A multiple regression of panel data model using fixed effects was estimated for each economic sector, both with and without robust standard errors, for a total of ten models. Fixed effects were used to control for the numerous factors inherently affecting sector-specific employment as well as electricity prices from state to state that have not been accounted for in the independent variables included in this study. The result is a conservative estimate of the isolated national effect of the variable of interest, real electricity prices on employment by industry.

The multiple regression of panel data model with fixed effects can be generally given by,

$$Y_{it} = \beta_0 + \sum_{j=1}^{k-1} \beta_j X_{jit} + \alpha_i + \varepsilon_{it}$$

Where i and t index states and years, such that y_{it} is the dependent variable of interest, employment by industry, in state i in year t, β_0 is the constant y intercept across all states, X is a k by 1 vector of explanatory variables, $\beta_j X_{jit}$ is the product of the observation for each independent variable j through k for state i in year t and the coefficient of X, k is the total number of included independent variables, α_i is the time-invariant fixed effect for state i, and ε_{it} are the residuals, and where $\varepsilon_{it} \sim N(0, \sigma^2)$, or are approximately normally distributed with a mean of zero.

β_j

β_0

Note that the 95% confidence intervals for β_j equal $\beta_j \pm \sigma$

Note that with the large p-value for PCPI, the 95% confidence interval extends from negative to positive, and thus includes zero, or no effect. Thus, we are uncertain of the effect of local income levels on employment in this industry.

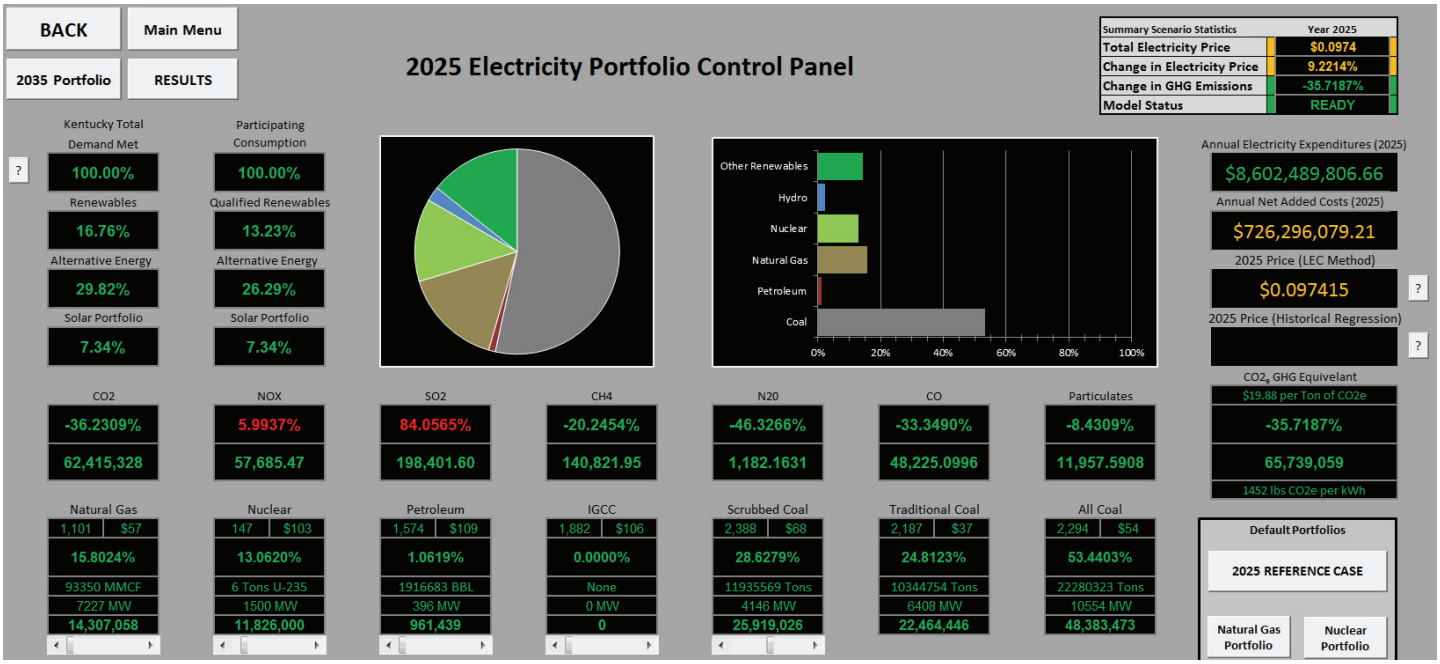
Portfolio Model Exercise

Kentucky Electricity Portfolio Model Exercise

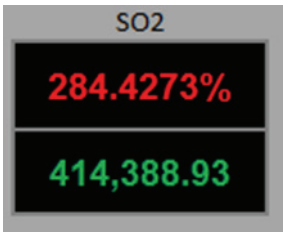
Exercise 1 (15 Minutes)

You and your teammates have been elected to manage Kentucky's electricity generation portfolio; however, the public has demanded 10% renewable electricity. Using the 2025 Electricity Portfolio Control Panel (keyboard shortcut <Ctrl P>) use only the toggles below renewable energy resources to adjust the allocation to each in order to achieve a qualified 10% Renewable Portfolio Standard (RPS). However, be sure to minimize any increases on the price of electricity (measured in $ per kWh), which will cause industry to leave the state and job losses, as well as to maximize reductions of Green House Gas (GHG) emissions (measured in tons of CO_{2e}), which is attributed to global climate change.

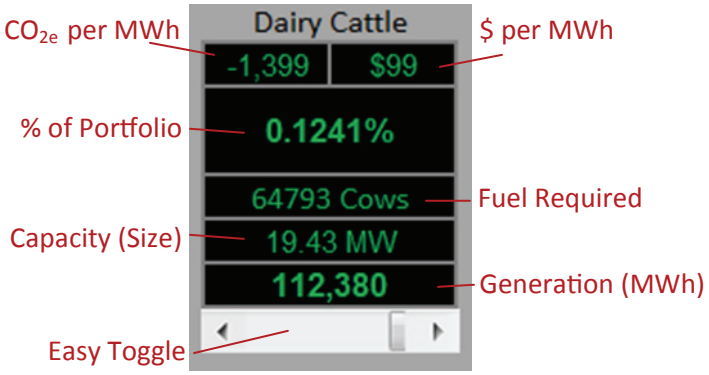


The portion of the portfolio that is specified as "qualified renewables", which excludes Kentucky's existing hydroelectric dams, is shown on the top left. Keep an eye on "Total Electricity Price" and CO_{2e} GHG Equivalent at the top right. For now, do not adjust non-renewable technologies or DSM. Do not change cost or other assumptions. You may not increase emissions of harmful pollutants such as sulfur dioxide (SO_2) or nitrous oxides (NO_X), which cause health problems and death.

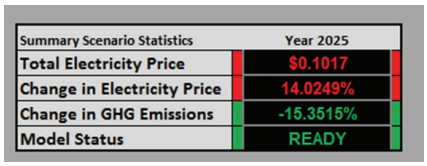
More SO_2 is Bad



Less SO_2 is Good



When you are satisfied with your portfolio, or when you run out of time, take a screen shot, or use a scrap piece of paper, to record the percentage of generation that you have allocated to each energy resource, the resulting price per kWh, and the resulting emissions (tons of CO_{2e}, SO_2, and NO_X). Be prepared to discuss your results and why you chose the portfolio you did.



This is actually a very difficult task since there are innumerable combinations possible portfolios. In our new 2014 model, our fastest computer can take several hours to optimize each portfolio. You have 15 minutes.

Exercise 2 (10 Minutes)

Build upon your existing 10% RPS by exploring the potential for Demand Side Management (DSM) to contribute to further emission reductions by moving the DSM toggle to the right. Use keyboard shortcut <Ctrl E> to explore the specific types of energy efficiency being used in the background of your simulation and answer the following questions.

What effect to DSM programs have on emissions?

What effect do DSM programs have on costs, (i.e. total expenditures in $)?

What effect do DSM programs have on electricity prices ($ per kWh)?

Using the efficiency portfolio at the top, and controls for individual economic sectors and specific programs below, achieve a 15% Renewable and Energy Efficiency Portfolio Standard (REPS), with 10% renewables and 5% energy efficiency. Be sure to minimize the impact on electricity and maximize emissions reductions. Do not change program costs. Note that as you lower end use, the share that is renewables may increase. You only need 10%.

When you are satisfied with your efficiency portfolio, use keyboard shortcut <Ctrl P> to return to the 2025 Portfolio. You may want to adjust the renewables you used since efficiency programs will change the amount of electricity generated. You may not adjust non-renewable technologies. Be sure to take a screen shot or somehow record the percentage of generation that you have allocated to each energy resource, the resulting price per kWh, and the resulting emissions (tons of CO_{2e}, SO_2, and NO_X)

Exercise 3 (15 Minutes)

From the 2025 Portfolio screen, use any combinations of technologies or fuels, renewable or otherwise, to attempt to achieve a greater reduction in greenhouse gas emissions, a lower price per kWh, lower sulfur dioxide emissions, lower nitrous oxide emissions than you were able to in Assignments 1 or 2. When you are satisfied with your portfolio, take a screen shot, or use a scrap piece of paper, to record the percentage of generation that you have allocated to each energy resource, the resulting price per kWh, and the resulting emissions (tons of CO_{2e}, SO_2, and NO_X). Answer the following questions.

Is it possible to achieve more reductions of GHG's with non-renewables than renewables?

Is it cheaper to reduce GHG's with non-renewables or renewables?

What seem to be the best to reduce GHG's at low costs, and is this surprising to you?

Exercise 4 (10 Minutes)

Without changing your portfolio at all, you should perform a sensitivity analysis by testing what impact some of the highly variable and less predictable input factors—including weather, population, income, and fuel prices—might be having on your scenario results. Use keyboard shortcut <Ctrl W> to jump to the Weather Control screen. Notice the price of electricity in the top right hand corner. Use keyboard shortcut <Ctrl N> to randomize all variable input factors, including weather which is shown on this screen. Now perform a 10 round Monte Carlo Simulation by randomizing all of the input variables 10 times, using the keyboard shortcut <Ctrl N>, and record the resulting price of electricity for each round. Note the minimum, maximum, and average price of electricity that resulted from these rounds and be prepared to discuss the results.

Wrap Up

If you have extra time, please return to the Portfolio Control Panel, keyboard shortcut <Ctrl P> and discuss what you might have done differently or better. From the Portfolio Control Panel, you can run additional Monte Carlo rounds by pressing <Ctrl N> to reload randomized input assumptions.

Exercise 1

Qualified Renewables	2025 Price	Electricity Expenditures	Net Added Costs	CO_{2e} equivalent	NO_x	SO_2
%	¢/kWh	$	$	tons	tons	tons
Fuels	**Natural Gas**	**Nuclear**	**Petroleum**	**IGCC**	**Scrubbed Coal**	**Traditional Coal**
%
